Multi portal concept

The multi-portal concept has been introduced to allow the deployment of several company or organization portals within the same application server.

One important constraint in such a model is that each portal should be able to share some portlets and some non secured resources with other portals but still beeing able to own their own critical resources such as dedicated datasources to reach a remote database.

In the the previous picture each portal or portlet is infact a Web ARchive (WAR) that can be hot deployed in the same application server. When a user request a page from one portal this one will returned an aggregated content that may content some markup generated by a shared portlet.

One obvious advantage of such a model is its use in an hosting environement.
